**Measuring Spasticity in people with DoC - from the lab to the bed side**

Anand Pandyan, Rasheed Meeran, Raymundo (Ray) Milay and Adam Poulter  
Keele University  
[a.d.pandyan@keele.ac.uk](mailto:a.d.pandyan@keele.ac.uk)

School of **HEALTH** and **REHABILITATION** 

**A plan of sorts**

- Spasticity and approaches to measure this
- Is there a reason to change current clinical approaches to measurement
- Measurement challenges in DoC

School of **HEALTH** and **REHABILITATION** 

**Spasticity – a conceptual definition**

Disordered sensori-motor control, resulting from an upper motor neurone lesion, presenting as intermittent or sustained involuntary activation of muscles

Pandyan et al 2005 Disabil & Rehab – SPASM consortium

School of **HEALTH** and **REHABILITATION** 

**Spasticity (operational definition)**

- Spasm (A transient but continuous muscular contraction with cutaneous or visceral triggers)
- Clonus (A transient but intermittent rhythmic or muscle contraction with proprioceptive and/or cutaneous triggers)
- Stretch induced muscle activity
- Abnormal movement patterns & co-contraction still remain unresolved

School of **HEALTH** and **REHABILITATION** 

Score	Penn spasm frequency scale	Spasm frequency score
0	No spasms	No spasms
1	Mild spasms at stimulation	One or fewer spasms per day
2	Irregular strong spasms less than one time/hour	Between one and five spasms per day
3	Spasms more often than one time/hour	Five to less than 10 spasms per day
4	Spasms more than 10 times/hour	Ten or more spasms per day, or continuous contraction

**Table 4:** The descriptors associated with the ordinal level scales used to quantify the frequency of spasms.  
Penn RD et al 1989 Intrathecal baclofen for severe spinal spasticity. N Engl J Med. 320: 1517 – 1521. Snow BJ et al 1990 Treatment of spasticity with botulinum toxin: a double blind study. Ann Neurol, 28: 512 – 515. Biering-Sørensen et al 2005 Spasticity-assessment: a review. Spinal Cord, 44: 708 – 722.

School of **HEALTH** and **REHABILITATION** 

**Tardieu method for measuring spasticity**

**Quality of muscle reaction (X):**

- 0 No resistance throughout the course of the passive movement
- 1 Slight resistance throughout the course of the passive movement, with no clear catch at precise angle
- 2 Clear catch at precise angle, interrupting the passive movement, followed by release
- 3 Fatigable clonus (< 10 seconds when maintaining pressure) occurring at precise angle
- 4 Infatigable clonus (> 10 seconds when maintaining pressure) occurring at precise angle

Gracies et al., 2000, Boyd & Ada 2001, Morris 2002

### Stretch induced muscle activity

Malhotra et al (2008) & personal data

School of HEALTH and REHABILITATION

### Contractures – a definition (& a digression)

A pathological condition of soft tissues **characterised by stiffness** and is usually associated with **loss of elasticity** and **fixed shortening** of the involved tissues (muscle, tendon, ligament, subcutaneous tissue, skin, blood vessels and nerves) and results in **loss of movement around a joint**

Harborn and Paller (1993); Teasell and Gillen (1993); Lehmann et al (1989); Botte et al (1988)

School of HEALTH and REHABILITATION

### Does spasticity cause contractures?

Lessons from observing stroke patients with sever levels of disability

School of HEALTH and REHABILITATION

### Had no function or spasticity

- Female – 74
- Total Anterior Circulatory Infarct
- NIHSS – 17 (Arm = 4, Leg = 2)

	Pre-Stroke	Admission	Baseline	3 Months	6 Months
Barthel	20	3	11	17	18
ARAT	57	0	0	0	0

EUROSS (2012 – 2014)

School of HEALTH and REHABILITATION

### .....did not develop contractures

EUROSS (2012 – 2014)

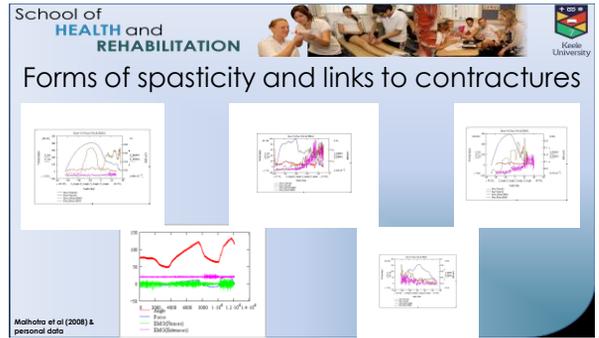

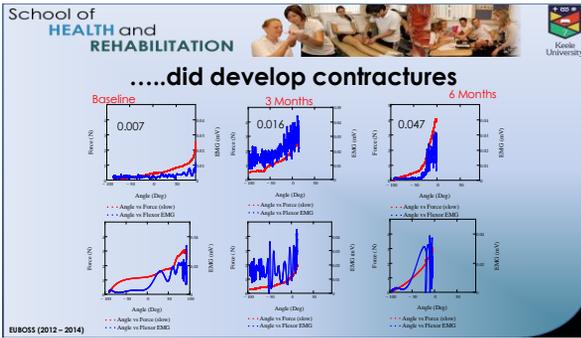

School of HEALTH and REHABILITATION

### Had no function but developed spasticity

- Male - 81
- Partial Anterior Circulatory Infarct
- NIHSS – 13 (Arm = 4, Leg = 3)

	Pre-Stroke	Admission	Baseline	3 Months	6 Months
Barthel	20	1	4	3	3
ARAT	57	0	0	0	1

EUROSS (2012 – 2014)

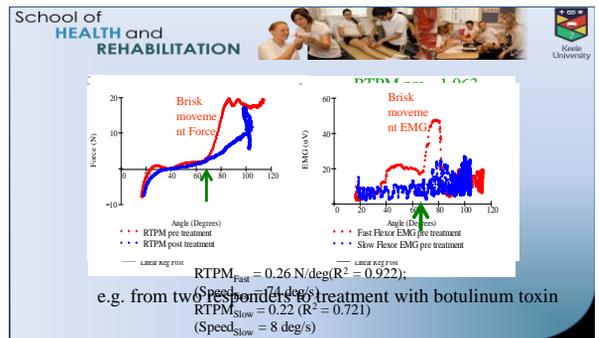

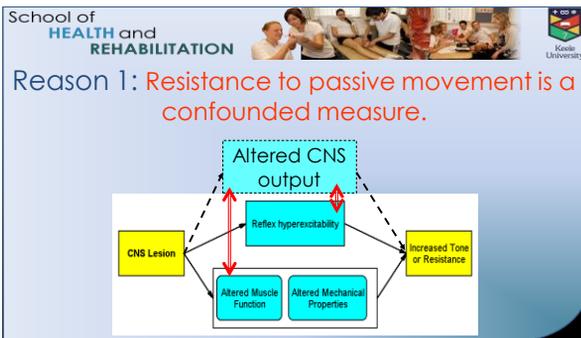

School of HEALTH and REHABILITATION 

### A summary of my thoughts on spasticity and contractures

- Spasticity may be an inevitable consequence of a neurological injury
- In patients with no functional movement atrophy is an inevitable consequence
- In patients with no functional movement and spasticity (or spastic dystonia) contractures may be inevitable

School of HEALTH and REHABILITATION 

### Should we measure stretch induced muscle activity as a measure of spasticity as opposed to using clinical scales?

School of HEALTH and REHABILITATION

Reason 2: Clinical scales are bad at identifying early spasticity

MAS	Abnormal muscle activity		EMG MAS	With	Without
	-ive	+ive			
0	12	44	+ive	43	1
1	0	21	-ive	44	12
1+	0	12			
2	1	3			
3	0	6			
4	0	1			

Sensitivity =  $43/(43+44) = 0.49$   
 Specificity =  $12/(12+1) = 0.92$

School of HEALTH and REHABILITATION

Reason 3: Treatment effects are often missed or underestimated

School of HEALTH and REHABILITATION

School of HEALTH and REHABILITATION

Case Report 1 – Patient A

- 72 year old gentleman
- Had a left MCA infarct with subsequent haemorrhagic transformation 3 days later
- Baseline measures taken 37 days poststroke
- No active movement of upper limb

School of HEALTH and REHABILITATION

Patient A - baseline

Elbow MAS = 0      Wrist MAS = 1+

- Elbow - Very slight velocity dependent response
- Wrist - Marked velocity and position dependent response to passive stretch
- No pain reported
- No active movement at elbow or wrist
- ARAT = 0/57

School of HEALTH and REHABILITATION

Patient A – Week 4

Elbow MAS = 3      Wrist MAS = 3

- Elbow – position dependent spasticity
- Wrist – velocity and position dependent spasticity
- Moderate pain
- No active movement
- ARAT = 0/57
- BoNTA (total Onabotulinumtoxin 400U) given 5 days after this assessment

School of HEALTH and REHABILITATION

### Patient A – Week 8 (&12)

Elbow MAS = 3      Wrist MAS = 4

- Elbow – no spasticity
- Wrist – position dependent spasticity
- Pain “couldn’t be any worse”
- No active movement
- ARAT 0/57

School of HEALTH and REHABILITATION

Clinical Rehabilitation 2002; 16: 654-660

### Are we underestimating the clinical efficacy of botulinum toxin (type A)? Quantifying changes in spasticity, strength and upper limb function after injections of Botox® to the elbow flexors in a unilateral stroke population

Measuring spasticity in DoC

Keelso University

BACKGROUND

- Holy Cross Hospital (HxH): 40 beds - 18 are in Disorders of Consciousness (DOC).
- Majority of patients in HxH suffer with spasticity.
- Current rx....
- Modified Ashworth Scale (MAS) – measuring tool for spasticity.
- Problem –difficult to reproduce, inter-rater reliably (1).
- Lacks sensitivity – basic assessment tool for a complex issue.

AIMS/OBJECTIVES

- Is the Biometrics Ltd. DataLog MWX8 accurate, reliable, and practical in measuring spasticity in a clinical setting?
- Can these methods of measurement inform clinical decision making?

PATIENT GROUP

- Vegetative State
- Diagnosed with TBI or Hypoxic Brain Injury
- Unilateral or bilateral elbow flexor spasticity/stiffness.
- MAS score  $\geq 1$  elbow flexors
- Able to be seated for measurement purposes

## PATIENTS SELECTED

- A sample of 3 patients.
- **Patient 1 – Botulinum Toxin A Injection**
  - The patient has had regular botulinum toxin injections in the past to treat the elbow flexor spasticity.
  - The patient had a course of injections during the surface EMG measurement period.
- **Patient 2 – Splint intervention**
  - The patient has bilateral fibreglass elbow splint to control bilateral elbow flexor stiffness.
  - The patient has had BoNT-A injections in the past for the elbow flexors but is 4 months post injection during the period of surface EMG measurements.
- **Patient 3 – Passive stretching regime**
  - The patient has had BoNT-A injections in the past for the left elbow flexors but is 4 months post injection during the period of surface EMG measurements.
  - The patient is only receiving manual passive stretching regime to maintain elbow range.

## MEASUREMENTS

### Pre-measurement protocol:

- No infection.
- Trache care/suction 30 mins prior.
- Sat out for minimum 1 hour before measurements.
- Patient should be settled and not agitated (as much as possible).
- Measurements completed in wheelchair.
- Pillows and lateral support removed.
- Electrodes applied to motor points as per BoNT-A injection manual.
- Measurements completed in the physio gym.

## MEASUREMENTS CONTINUED....

Same protocol for all patients before and after intervention.

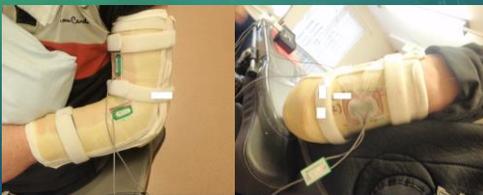

### Six channels to be used:

- Channel 1: Biceps brachii EMG through metal electrodes.
- Channel 2: Brachioradialis EMG through metal electrodes.
- Channel 3: Triceps EMG through metal electrodes.
- Channel 5: Stretch force applied through force transducer.
- Channel 6: Joint angle measurements through angle sensor.
- Ground channel.

## EXAMPLE OF MEASUREMENT SETUP

## MEASUREMENT SETUP FOR SPLINTING CONDITION

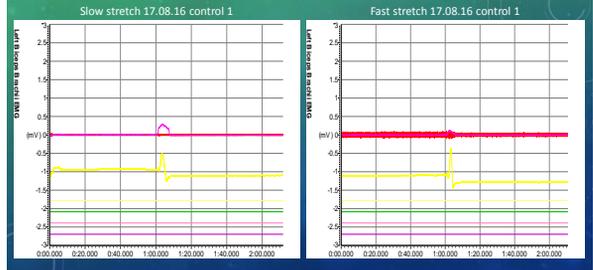

## STANDARD MEASUREMENTS FOR ALL PATIENTS

- **Measurement 1**
  - Passive slow stretch (roughly 10 seconds from resting position to end range)
  - 1 minute baseline without stimulus -> slow stretch to end range-> release -> record for a further 1 minute.
- **Measurement 2**
  - Passive fast stretch (roughly 5 seconds from resting position to end range)
  - 1 minute baseline without stimulus -> fast stretch to end range-> release -> record for a further 1 minute.
- **Slow stretch always completed prior to fast stretch.**

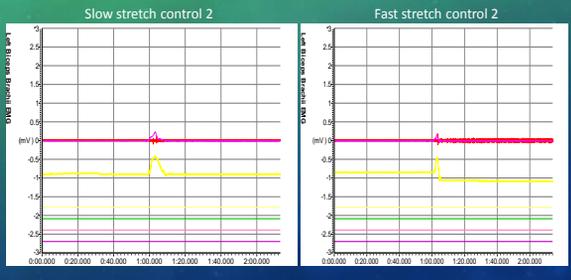

### ADDITIONAL MEASUREMENTS

- **Patient 1:**
  - Measurements obtained pre- BoNT-A injection.
  - Measurements 7-14 days post BoNT-A injection and 1 month
- **Patient 2:**
  - Measurement 1+2 pre-application of elbow splint.
  - Applied splint.
  - 5 min measurement of channels 1-3 (Immediately after splint application)
  - 2 hourly 5 min measurements (channels 1-3) for a period of 4 hours.
  - Repeat measurement 1+2 immediately after removal of splint.
- **Control group:**
  - Measurements obtained from staff

### NORMAL SUBJECTS

### NORMAL SUBJECTS

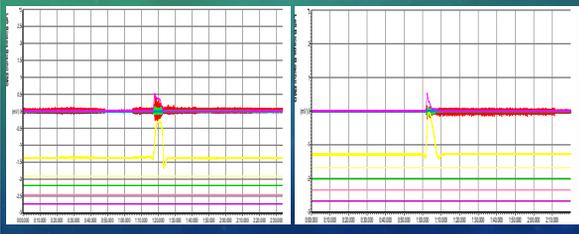

### PATIENT 1 RESULTS

### COMPARING PRE AND POST BOTOX

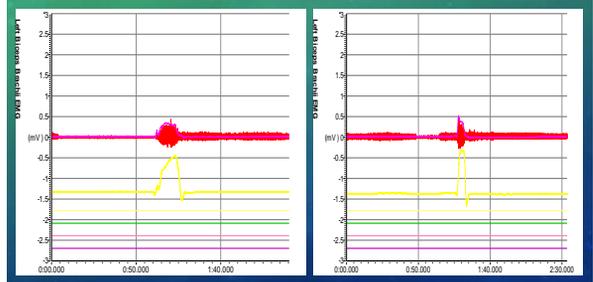

Pre Botox 29/06/16 (fast stretch)

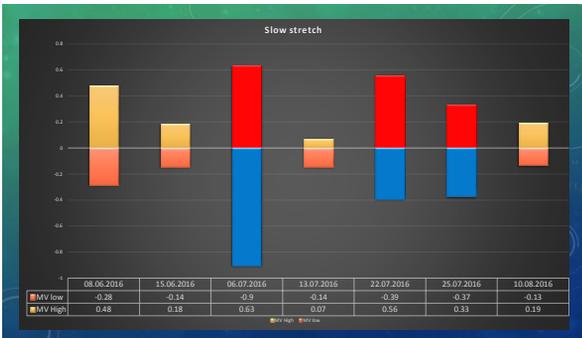

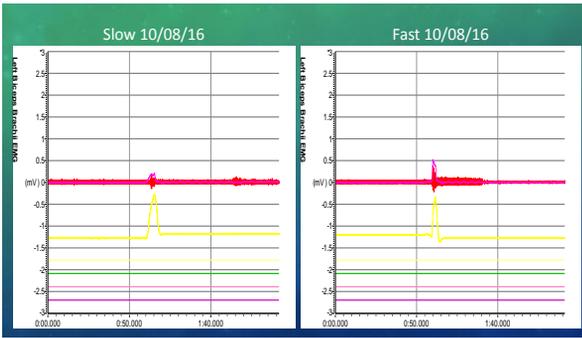

Post Botox 25/07/16 (fast stretch)

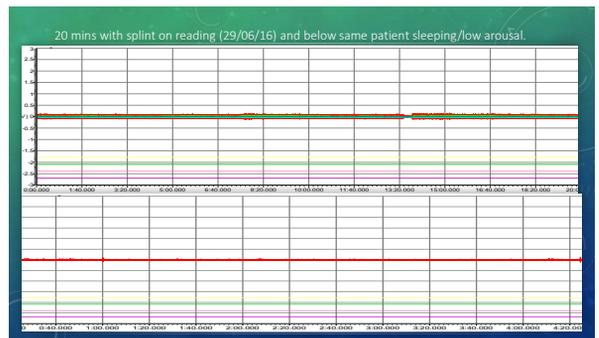

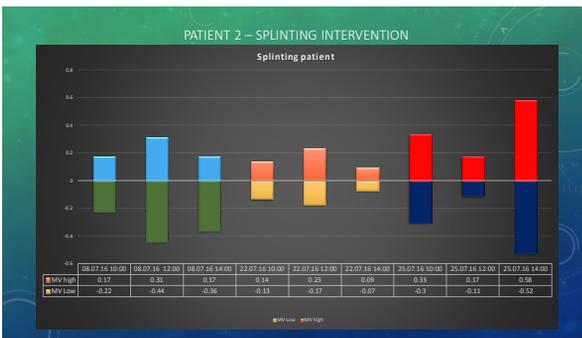

Slow stretch 29/06/16

Fast stretch 29/06/16

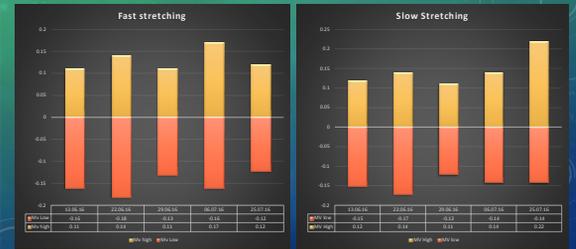

PATIENT 2 RESULTS

## PATIENT 3 RESULTS

### GRAPHS FOR PATIENT 3

## CONCLUSIONS

- Following injections on BoNT-A amplitude was reduced
- Not all patients are demonstrating spasticity – see patient 2, should they have had Botox?
- Low arousal demonstrates a reduced amplitude in EMG readings.
- We are not able to effectively assess splinting with the current technology.
- Can measure for 20 minutes in splinting condition – longer periods may cause marking/sores.
- Some of the background artefacts on the readings – are these due to methodology or fibrosis/adipose tissue.
- No demonstration of “catch” (patient 3) on graphs despite being rated MAS 1

## LIMITATIONS

- Initially took 1 hour to complete readings.
- Extensive practice and training required for specific protocol and use of equipment.
- To monitor effect of splinting a patient's splint had to be modified to fit electrodes without splint removal.
- Requires certain conditions to gain useful readings, i.e. patient alert, trache care completed, no coughing.
- Connectivity issues - need to use laptop to check settings before reading.
- Difficult to transfer data if collected on SD card – mostly due to IT security in hospitals (cannot use USB or card reader).
- Often if left unattended the laptop would go into standby, causing the Bluetooth signal to be lost.

## IMPLICATIONS FOR PRACTICE

- Reduced application to measurement time to 15-20 mins per limb
- Useful as an adjunct to MAS to review individual muscle groups.
- Can be completed in sitting with one therapist but much faster with two.
- Can give more specific results over time and give a numerical objective value.
- Useful in clinical decision making regarding BoNT-A injections – spasticity vs contracture.
- Better equipment:
  - Wireless electrodes, goniometer and force transducer – facilitate set up and ease of measurement
  - Bluetooth connectivity issues – loss of connection, unable to transfer data wirelessly
  - Datalog software compatibility – only runs on Windows 7

## FUTURE RECOMMENDATIONS

- Re-test muscle groups where there are anomalies (yawning or low arousal).
- A longer (4-6 hours) reading may be of benefit in the splinting condition, however we were limited by marking on the skin due to the electrodes.
